(54) Title: METHOD AND SYSTEM FOR LOAD SHARING BETWEEN A PLURALITY OF CELLS IN A RADIO NETWORK SYSTEM

(57) Abstract: The present invention relates to a method and a system for load sharing between a plurality of cells in a radio network system, wherein each of said cells is serving a number of mobile devices. For handover of a mobile device from a currently serving source cell to a target cell, a prioritisation among cells adjacent to the source cell is carried out by calculating the power budgets between the currently serving source cell on the one hand and said adjacent cells on the other hand, and the adjacent cell having the highest priority is selected as target cell.

**Method and system for load sharing between a plurality of cells in a radio network system**

5

FIELD OF THE INVENTION

10 The present invention relates to a method and a system for load sharing between a plurality of cells in a radio network system, wherein each of said cells is serving a number of mobile devices.

BACKGROUND OF THE INVENTION

15

Traffic management in mobile cellular networks comprises a set of features whose final purpose is the redistribution of the mobile devices in the cells so that the probability of congestion and blocking is reduced and, thus, capacity is increased and quality is improved.

20

In current systems, the design is based on the hypothesis of a uniform distribution of served mobile devices. However, such assumption may be far from reality. Namely, the flexibility resulting from the existing large set of parameters included in the different algorithms related to traffic distribution can not be fully seized  
25 because of its complexity. The large set of available parameters makes the detailed planning process on a cell-by-cell basis a time-consuming work.

As a consequence, operators fix parameters to a common set of default values shared between the cells even if the performance and capacity is not achieved in  
30 an optimum way. Moreover, a few operators extend the parameter optimisation by classifying the cells in accordance with certain scenarios like rural, urban, tunnel, indoors etc. and/or in accordance with the layer/band used (like Macro900/1800, Micro900/1800, Pico1800, Motorway900). So, the cells are divided into scenario

- 2 -

groups or layer/band groups, and common default parameter values are shared which, however, are not optimum.

5 In those cases where existing features for traffic balance and congestion relief are difficult to optimise, just a few parameters are taken into account for optimisation which requires so-called field trials. During the tuning process, conclusions from parameter changes are difficult to derive, and final settings are nearly always on the safe side with its limited results. Moreover, such trials are normally focused on global parameters of features under study, and parameter optimisation of adjacent  
10 cells is hardly ever done. So, differences between adjacent cells are rarely considered due to a high effort required. Therefore, the potential of so-called adjacency parameters is not fully exploited.

15 A final limited parameter tuning based on cell/area level performance indicators is normally carried out only over those cells where performance problems are existing.

Even if an optimum value were reached by means of the above-mentioned trials, changes in traffic or environment conditions, like the installation of new cells,  
20 changes of interference level by frequency re-planning etc., would force a further re-tuning process of the parameter base, where no automatic reactive process is currently in use. Such a situation could be analysed as a result of slow trends, like the change of the number of user registrations, or fast changes, e.g. of the number of connections, during a short time period, like an hour or a day.

25 One of the critical causes of network variations is interference. Differences in propagation conditions between cells or changes in the frequency plan will produce variations in time or space. Adaptation to this variations would increase network performance, but would also require a very high tuning effort.

30 US 5,241,685 A discloses a load sharing control for a mobile cellular radio system so as to achieve a load sharing between a first cell and a second cell adjacent to

- 3 -

the first cell where each cell is serving a number of mobile devices. The first cell has a predetermined entering threshold which is a function of the received signal strength for mobile devices entering this cell from the second adjacent cell by means of handoff. A certain occupancy level indicates the occupied channels in relation to the available channels in the cell. For handover, the occupancy level of the first and second cells are determined, and it is further determined whether the second cell has a lower occupancy level than the first cell. Then, an entering threshold level for the second cell is determined which is a function of the received signal strengths for the mobile devices in the first cell about to enter the second cell. The entering threshold for the second cell is decreased if the occupancy level of the second cell is found to be lower than the occupancy level of the first cell, whereby the border between the first and second cells is dynamically changed. So, in this known system, the redistribution of the users for congestion relief is usually achieved by shrinking loaded cells through temporarily reduced margins for handovers between adjacent cells.

However, this prior art system has the disadvantages of reduced quality in traffic receiving cells and reduced overlapping in activation periods wherein the latter results in ping-pong problems.

20

### SUMMARY OF THE INVENTION

It is an object of the present invention to improve the load sharing between a plurality of cells in a radio network system, in particular by taking congestion relief with quality constraints into account.

25

In order to overcome the above and further objects, according to a first aspect of the present invention, there is provided a method for load sharing between a plurality of cells in a radio network system, wherein each of said cells is serving a number of mobile devices, characterized in that, for handover of a mobile device from a currently serving source cell to a target cell, a prioritisation among cells adjacent to the source cell is carried out by calculating the associated power

30

- 4 -

budgets between the currently serving source cell on the one hand and said adjacent cells on the other hand, and the adjacent cell having the highest priority is selected as target cell.

- 5 According to a second aspect of the present invention, there is provided a system for load sharing between a plurality of cells in a radio network system, wherein each of said cells is serving a number of mobile devices, characterized by means for calculating the power budgets between a source cell which is currently serving a mobile device to be handed over to a target cell on the one hand and cells  
10 adjacent said source cell on the other hand, means for priorisation among said adjacent cells in accordance with the result calculated by the calculating means, and means for selecting the adjacent cell having the highest priority as target cell.

- So, in accordance with the present invention, once a handover is triggered,  
15 candidate cells are prioritised by calculation of their associated power budget margins.

- An advantage of the present invention is that traffic and environment changes are tracked by means of automatic parameter auto-tuning in order to achieve the best  
20 performance without user interaction. As a consequence, less parameters are required to be adjusted. Further, the margins can be smoothly changed so that there is a smooth behaviour of the load sharing control. Moreover, the present invention provides for a better performance since quality and overlapping constraints are included together with capacity constraints so as to add more  
25 information in the control of the operational area of the cells concerned. In particular, better control of the operational area of the cells is achieved as adjacent parameters control the shape of the cell, and adaptation to cell differences can be easily carried out.

- 30 In particular, the final prioritising criterion is the received downlink power difference from a beacon channel.

- 5 -

In a preferred embodiment of the invention, the power budget PBGT (n) of the nth cell ( $n = 1, 2, \dots, N; N > 1$ ) is calculated by using the equation

$$\text{PBG T}(n) = \text{RxLev}_{\text{adj}} - \text{RxLev}_{\text{serv}} - \text{HoMarginPBG T}_{\text{serv}}(\text{adj}) \quad (1)$$

5

wherein  $\text{RxLev}_{\text{adj}}$  is the receiving level of the adjacent cell,  $\text{RxLev}_{\text{serv}}$  is the receiving level of the current serving source cell and  $\text{HoMarginPBG T}_{\text{serv}}(\text{adj})$  is a handover margin parameter.

- 10 In a preferred embodiment, the prioritisation is carried out by taking into account both load and quality performance. So, displacement of overlapping area between adjacent cells may be controlled by both load and quality indicators, while overlapping may still be assured if the sum of margins is maintained unchanged. When using the above equation (1), the handover margin parameter
- 15  $\text{HoMarginPBG T}_{\text{serv}}(\text{adj})$  should be a function of both load and quality performance.

Usually, when the currently serving source cell is congested, its operational size is reduced.

20

- The shrinking of the operational size of the cell concerned can be performed by means of relaxing handover conditions to the neighbouring cells. This action can be translated into a decrement of the  $\text{HoMarginPBG T}_{\text{serving} \rightarrow \text{adj}}$  parameters to adjacent cells. In the inverse direction of the 'adjacency', opposite action must be
- 25 carried out for the  $\text{HoMarginPBG T}_{\text{adj} \leftarrow \text{serving}}$  parameters of the adjacent cells, namely such parameters are incremented, so as to maintain constant overlapping areas between involved cells. Due to the fact that constant overlapping between involved cells may be desirable in order to avoid ping-pong effects, simultaneous adjustment of symmetric parameters should be carried out to modify by the same
- 30 amount, of course to opposite direction. In this way, saturation in the adjacency only in one direction, caused by reaching operator constraints in parameter values, may easily be considered.

- 6 -

The present invention can be implemented in any kind of cellular mobile network systems like i.e. GSM or UMTS, or in internet protocol radio access networks. It should be also noted that the invention can be implemented in a multiradio  
5 environments where many different air interference protocols are used.

### BRIEF DESCRIPTION OF THE DRAWINGS

10 In the following, the present invention will be described in greater detail based on a preferred embodiment with reference to the accompanying drawing Figures in which

Fig. 1 is a schematical diagram showing a process for the final parameter setting. The proposed final values (i.e.:output) for the adjacency  
15 automated margins are derived from congestion and quality indicators of serving and adjacency target cells. From differences of both indicators, a conclusion for changes in involved parameters is drawn;

20 Fig. 2 shows an example of a table showing percentage of samples in predefined defined downlink quality (columns) and received level intervals (rows) ;

25 Fig. 3 shows a three-dimensional plot indicating a cumulative density function extracted based on samples from the previous table, and a graphical representation of how a conclusion for the minimum required level is drawn from the quality requirements;

30 Fig. 4 shows a graph indicating the curve which represents the intersection between surfaces in the previous figure, where it is clearly seen the relationship between required quality and minimum required level;

- 7 -

Fig. 5. shows a graph indicating the differences between adjacent cells in terms of, required level for a certain quality (i.e.: Quality-to-Minimum Level mapping). Averaging over quality values more likely to happen is carried out to calculate a final unique global indicator of the difference; and

Fig. 6 shows a block diagram of a preferred embodiment of a control structure for power budget margin automation in accordance with a preferred embodiment of the present invention.

#### DESCRIPTION OF THE PREFERRED EMBODIMENTS

An automatic tuning process for handover margins used in a target-cell prioritisation algorithm is here described.

In radio access networks, candidate cells are prioritised through calculation of their association power budget. Discarding minor compensation terms, the evaluation of this indicator uses the equation

$$PBGT(n) = RxLev_{adj} - RxLev_{serv} - HoMarginPBGT_{serv}(adj) \quad (1)$$

wherein  $RxLev_{adj}$  is the receiving power level of the nth adjacent cell,  $RxLev_{serv}$  is the receiving power level of the currently serving source cell, and  $HoMarginPBGT_{serv}(adj)$  is a handover margin parameter.

The remaining adjacent handover margin parameter  $HoMarginPBGT_{serv}(adj)$  is normally used to assure hysteresis (i.e. overlapping) region to avoid instabilities from ping-pong problems. In best cases, some operators bias the priority evaluation to cells belonging to capacity layers (i.e. micro and pico cells). In some

- 8 -

situations, scenario considerations (e.g. average interference in tight frequency reuse, propagation severity differences in indoor-outdoor environments / 900-1800 MHz bands) may also be included by experienced operators, but no differences between cells in the same class or time periods are accounted for.

5

A control method for this handover margin parameter is provided in order to achieve prioritisation of adjacent cells taking into account differences in the signal level requirements. Thus, displacement of overlapping area between adjacent cells is controlled by both load and quality indicators, while overlapping may still be  
10 assured if the sum of margins is maintained unaltered. Doing so, the space of the cell is controlled.

A key factor resides on the ability to define a mapping function between received downlink level from BCCH channel (broadcast control channel) and predicted  
15 quality of assigned channel. This function will make use of mobile measurement reports extracted dynamically from the network, easily differentiating among cells or time. In this way, the automation algorithm will cope with scenario differences (i.e. interference, propagation severity) due to traffic trend changes both in space and time.

20

Fig. 1 schematically shows a tuning process for providing minimum level thresholds from measurement reports wherein in particular shown is the flow of information from the network to the final parameter setting. Collection of mobile measurements from users in connected mode is undertaken in every cell. By  
25 means of further processing of these raw counters, the probability density function  $PDF=f_{cell}(Received\ Level, Perceived\ Channel\ Quality)$  construction is straightforward.

A tabular representation is depicted in Fig. 2 showing an example of a table  
30 structure of *RxLev/RxQual* counters from *Rx-level* statistics (TRX level, downlink),

- 9 -

wherein *RxLev* is the receiving level and *RxQual* is the receiving quality and the *Rx-Level* is the receiving level.

From this piece of information, the probability of perceiving at least a certain  
5 connection quality may be extracted for every measured received level. This three-  
dimensional function is depicted in figure 3 showing a three-dimensional plot of  
cumulative *RxQual* distribution from *Rx-Level* statistics on the basis of samples  
extracted from real data. So, this figure shows the appearance of cumulative  
quality distribution (i.e. probability of getting quality better than a certain value), for  
10 every level band. In the example, upper limits for 1,2,3,4,5,6 level bands are -100,  
-95, -90, -80, -70 and -47dBm, respectively. It is worthwhile to note that they were  
extracted from a real network management system database. The intersection  
between *Confidence* and *RxLevel-RxQual* three-dimensional planes is the aimed  
relationship *Quality-to-Level*.

15

Once this *Level-to-Quality* relationship has been constructed, the next steps will  
aim at building the inverse *Quality-to-Level* function.

First, the confidence of the mapping process must be decided. The meaning of  
20 this internal parameter of the algorithm relates to the likelihood of the decision that  
a certain level is enough to get a predefined quality. Its graph is a plane whose  
intersection with the three-dimensional probability function defines a unique curve  
relating target connection quality to minimum required level (i.e.: *Quality-to-Level*  
relationship), represented in Fig. 4.

25 From this relationship, the comparison between cells is rather straight-forward,  
which is shown in Fig. 5. Those cells that require a higher level to fulfill quality  
targets have their priority reduced in favour of those less power greedy. The  
adjacency handover margin should correspond to level differences between  
adjacent cells (equally distributed through both margins in the adjacency, still  
30 maintaining a constant residual term for overlapping).

- 10 -

The only remaining issue is the quality target which is used for level comparison purposes, as the quality cross point for handover is not known. Averaging of level values through quality values where handover may occur (i.e.: from *Q0* to *Quality Handover Threshold*) must be done to get a unique value which reflects the  
 5 difference in level requirements in the adjacency.

In Fig. 6, the basic structure of the proposed control module applied in adjacency basis for the parameter margin parameter  $HoMarginPBGT_{serving \rightarrow adj}$  and  $HoMarginPBGT_{adj \rightarrow serving}$  is presented.

10 In a first step, formulas are applied to raw counters in order to extract meaningful quality and congestion performance indicators from source (S) and target (T) cells. Either directly defining a cost function, or just defining thresholds for acceptable and non-acceptable situations (and building it in intervals with different slopes), operator controls the mapping function from raw counters to quality and capacity  
 15 problem indicators. A different mapping cost function is used to extract the problem indicators related to quality and congestion, while they can be possibly shared between cells.

The selected controller follows an incremental structure, proposing the increment/decrement from the previous values. Basically, when a cell is  
 20 congested, shrinking its operational size by means of relaxing handover conditions to neighbouring cells can be performed for traffic balancing between cells. This action is translated into a decrement in  $HoMarginPBGT_{serving \rightarrow adj}$  parameters to adjacent cells. In the inverse direction of the adjacency, opposite action must be carried out for  $HoMarginPBGT_{adj \rightarrow serving}$  parameters to maintain constant  
 25 overlapping between cells.

Due to the fact that constant overlapping between involved cells may be desirable in order to avoid ping-pong effects, simultaneous adjustment of symmetric parameters must be carried out to modify by the same amount (of course in opposite directions). In this way, saturation in the adjacency only in one direction,

- 11 -

caused by reaching operator constraints in parameter values, may easily be considered.

5 Being balance in problems (i.e. costs) between cells the last purpose of the automation action, the cost difference output controls the direction and magnitude of changes. This error signal related to problem indicator differences is to be minimised, as in most control systems. The equilibrium point will be reached when this cost error between cells is zero (not necessarily individual costs). As it may be seen from a closer analysis, this structure has a variable step size, proportional to  
10 deviation from stability final point.

In situations where trade-off is achieved (i.e.: serving cell is congested and adjacent cell has bad quality), cost terms of opposite sign compensate, whenever cost values for threshold crossing are consistent (i.e.: equal problem indicator for border problem). A final equilibrium point (i.e. cost difference equal to 0) can be  
15 biased by weighting problem indicator difference terms with two priority factors, taking into account operator preferences in term of quality or capacity priorities.

Calculated deviation from balance is adjusted by means of step control, selecting the aggressiveness of the tuning process, and thus influencing on the final trade-off between speed/stability of the convergence process to the final  
20 equilibrium solution. A subsystem in a higher level in the proposed hierarchical control architecture may govern the speed, based on instability detection (i.e.: oscillation in parameter values) or slow convergence.

Once deviation from current values is proposed, final checks must be done against maximum and minimum limits constrained by the operator.

25

Although the invention is described above with reference to an example shown in the attached drawings, it is apparent that the invention is not restricted to it, but can vary in many ways within the scope disclosed in the attached claims.

30

- 12 -

**Claims**

5 1. A method for load sharing between a plurality of cells in a radio network system, wherein each of said cells is serving a number of mobile devices, characterized in that,  
for handover of a mobile device from a currently serving source cell to a target cell,  
a prioritisation among cells adjacent to the source cell is carried out by calculating  
10 the power budgets between the currently serving source cell on the one hand and said adjacent cells on the other hand, and the adjacent cell having the highest priority is selected as target cell.

2. The method according to claim 1,  
15 characterized in that the final prioritising criterion is a received downlink power difference from a beacon channel.

3. The method according to claim 1 or 2,  
characterized in that the power budget PBGT(n) of the nth cell ( $n = 1, 2, 3, \dots, N$ ;  
20  $N > 1$ ) is calculated by using the equation

$$\text{PBG T}(n) = \text{RxLev}_{\text{adj}} - \text{RxLev}_{\text{serv}} - \text{HoMarginPBGT}_{\text{serv}}(\text{adj}),$$

wherein  $\text{RxLev}_{\text{adj}}$  is the receiving level of the nth adjacent cell,  
25  $\text{RxLev}_{\text{serv}}$  is the receiving level of the currently serving source cell, and  
 $\text{HoMarginPBGT}_{\text{serv}}(\text{adj})$  is a handover margin parameter.

4. The method according to at least any one of the preceding claims,  
characterized in that the prioritisation is carried out by taking into account both load  
30 and quality performance of said cells.

- 13 -

5. The method according to claims 3 and 4,  
characterized in that  $\text{HoMarginPBGT}_{\text{serv}}(\text{adj})$  is a function of both load and quality  
performance.
- 5 6. The method according to claim 5,  
characterized in that  $\text{HoMarginPBGT}_{\text{serv}}(\text{adj})$  is a function of a predetermined  
scenario.
7. The method according to claim 5 or 6,  
10 characterized in that  $\text{HoMarginPBGT}_{\text{serv}}(\text{adj})$  is a function of a predetermined  
hystereses.
8. The method according to at least any one of the preceding claims,  
characterized in that, when the currently serving source cell is congested, its  
15 operational size is reduced.
9. The method according to claims 3 and 8,  
characterized in that the parameter  $\text{HoMarginPBGT}_{\text{serving} \rightarrow \text{adj}}$  of the currently  
serving source cell is decremented.
- 20 10. The method according to claim 9,  
characterized in that the parameter  $\text{HoMarginPBGT}_{\text{adj} \rightarrow \text{serving}}$  of an adjacent cell is  
incremented.
- 25 11. A system for load sharing between a plurality of cells in a radio network  
system, wherein each of said cells is serving a number of mobile devices,  
characterized by  
means for calculating the power budgets between a source cell which is currently  
serving a mobile device to be handed over to a target cell on the one hand and  
30 cells adjacent to said currently serving source cell on the other hand,  
means for prioritisation among said adjacent cells in accordance with the result  
calculated by the calculating means, and

- 14 -

means for selecting the adjacent cell having the highest priority as target cell.

12. The system according to claim 11,  
characterized in that said prioritisation means uses a receiving downlink power  
5 difference from a beacon channel as a final prioritising criterion.

13. The system according to claim 11 or 12,  
characterized in that the calculating means calculates the power budget PBGT(n)  
of the nth cell ( $n = 1, 2, 3, \dots, N; N > 1$ ) by using the equation

10

$$\text{PBG T}(n) = \text{RxLev}_{\text{adj}} - \text{RxLev}_{\text{serv}} - \text{HoMarginPBG T}_{\text{serv}}(\text{adj}),$$

wherein  $\text{RxLev}_{\text{adj}}$  is the receiving level of the nth adjacent cell,  
 $\text{RxLev}_{\text{serv}}$  is the receiving level of the currently serving source cell, and  
15  $\text{HoMarginPBG T}_{\text{serv}}(\text{adj})$  is a margin parameter.

14. The system according at least any one of claims 11 to 13,  
characterized in that said prioritisation means carries out prioritisation by taking into  
account both load and quality performance.

20

15. The system according to claims 13 and 14,  
characterized in that  $\text{HoMarginPBG T}_{\text{serv}}(\text{adj})$  is a function of both load and quality  
performance.

25 16. The system according to claim 15,  
characterized in that  $\text{HoMarginPBG T}_{\text{serv}}(\text{adj})$  is a function of a predetermined  
scenario.

17. The system according to claim 15 or 16,  
30 characterized in that  $\text{HoMarginPBG T}_{\text{serv}}(\text{adj})$  is a function of a predetermined  
hystereses.

- 15 -

18. The system according to at least any one of claims 11 to 17,  
characterized by means for reducing the operational size of the currently serving  
source cell in case of a congestion.
- 5 19. The system according to claims 13 and 18,  
characterized by means for decrementing the parameter  $\text{HoMarginPBGT}_{\text{serving} \rightarrow \text{adj}}$   
of the currently serving source cell.
20. The system according to claim 19,  
10 characterized by means for incrementing the parameter  $\text{HoMarginPBGT}_{\text{adj} \rightarrow \text{serving}}$   
of an adjacent cell.
